AU 200213126 A A61F-009/01 Based on patent WO 200234178

Abstract (Basic): WO 200234178 A1

NOVELTY - A prospective **photorefractive** treatment is adjusted for a higher order or a lower order aberration, based upon a biomechanically or biodynamically induced deviation from the expected result for developing a treatment which compensates the biodynamically and biomedically induced deviation.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

(1) Higher order aberration correction method;
(2) Regression effect lessening method; and
(3) Refractive surgery system.

USE - E.g. **photorefractive** surgery, for correcting higher order aberration in consideration of biodynamical or biomechanical responses of the **eye** .

ADVANTAGE - Provides better objective and subjective evaluation of the **eye** . Enables modeling of **eye** for adjusting a treatment procedure for **vision** correction. Provides non-limiting benefit by removing the effects of **eye** rotation that occurs when a patient changes from a sitting to a supine position.

Abstract (Basic): WO 200128478 A2

NOVELTY - The laser beam spatial intensity profile comprises a flat portion extending for a larger percentage of the profile and symmetric about radius of profile. A rounded edge continuous with the flat portion, is extended for a smaller percentage of the profile, until

ablation intensity threshold is reached. The beam suitable for ablating **eye** tissue is projected to **eye** through the rounded edge.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

(a) Laser system;

(b) Aperture card for use in **photorefractive** laser system;

(c) Method for providing laser beam

USE - For refractive laser ablation systems and excimer laser ablation system used in **eye** surgery.

ADVANTAGE - Reduces the stair-step effect of typical ablation with square-sided ablation profile. Flat top assists in steepening ablation sides, hence haze that results from square profile ablations are reduced.

DESCRIPTION OF DRAWING(S) - The figure shows the laser refractive ablation system.

English Abstract
  A technique of refractive **eye** correction employs multiple steps to correct refractive errors in the **eye** . In the first step, gross decentrations of the refractive error are corrected, allowing the subsequent steps to be relatively symmetric in their treatment profile. Then, the **eye** 's refractive error is again measured, and a subsequent treatment is applied for the remaining error. The overall treatment is thus completed in two or more steps.

English Abstract
A system and method are provided in which an iris or **eye** image is taken during a refractive diagnostic analysis. The image is employed for aligning data from the analysis with data from other refractive analysis instruments, as well as aligning a refractive surgical tool, such as a laser, with the **eye** for treatment. Further, the stored iris image is compared with the patient's iris before treatment, verifying that the correct **eye** is to be treated with a developed treatment pattern. A variety of refractive instruments can be used, such as corneal topography systems and wavefront aberration systems.

English Abstract
A customized corneal profile is provided by combining corneal topography data with captured wavefront aberration data to form a course of refractive treatment of the **eye** . In one embodiment, the captured wavefront data is employed within the area of a pupil, while the corneal topography data is employed in the area outside of the pupil. In other embodiments, the topography data is adjusted based on the wavefront data, a course of refractive treatment is simulated and displayed upon the topography data, and an initial evaluation of the suitability of a patient for treatment is performed based on the topography data.

English Abstract
An improved wavefront sensor (300) is provided that enhances the initial focus and precision of imaged spots used to determine the monochromatic wave aberrations of the **eye** . The wavefront sensor includes an adjustment camera (323) that is independent of a lenslet camera (312). A laser (306) in a lower power mode is projected onto the retina of the **eye** and is brought into more precise or sharp focus by a control system employing data from the adjustment camera, which aids in focusing the imaged spots. "Trombone"-type optics (314) are used to adjust the focus of the light projected onto the retina and the imaged spots onto a sensor. The laser (306) has a higher power mode used when acquiring data of the imaged spots from the sensor.

US 20020082629	A1		A61B-018/20	Provisional application US 2000241869
AU 200213126	A		A61F-009/01	Based on patent WO 200234178

Abstract (Basic): WO 200234178 A1

NOVELTY - A prospective **photorefractive** treatment is adjusted for a higher order or a lower order aberration, based upon a biomechanically or biodynamically induced deviation from the expected result for developing a treatment which compensates the biodynamically and biomedically induced deviation.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

(1) Higher order aberration correction method;
(2) Regression effect lessening method; and
(3) Refractive surgery system.

USE - E.g. **photorefractive** surgery, for correcting higher order aberration in consideration of biodynamical or biomechanical responses of the eye.

ADVANTAGE - Provides better objective and subjective **evaluation** of the **eye** . Enables modeling of eye for adjusting a treatment procedure for vision correction. Provides non-limiting benefit by removing the effects of eye rotation that occurs when a patient changes from a sitting to a supine position.

Abstract (Basic): WO 200128476 A1

NOVELTY - Diagnostic **measurement** of patient's **eye** (12) is done. An image having an iris image (120) of the patient's eye is obtained. A spatial relationship between the image and the diagnostic measurement is determined. A refractive treatment is developed based on the diagnostic measurement. Another image of patient's eye is aligned to obtain spatial relationship with the previous image for performing refractive treatment.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

(a) A system for aligning a refractive correction instrument with a

patient's eye;
(b) Method for providing a course of refractive treatment;
(c) Method of aligning a refractive correction instruments with a patient's eye;
(d) System for aligning refractive diagnostic and treatment data;
(e) Method of aligning refractive tools;
(f) Method for eye alignment and characterization;
(g) System for alignment and **photo refractive** treatment of eye;

(h) Laser system
USE - For ophthalmic refractive surgery systems and iris recognition and location system.
ADVANTAGE - Minimizes severe changes in corneal curvature by sing tapering zone of partial ablation and hence lessons regression. Provides increased accuracy using ophthalmic refractory surgery techniques and ophthalmic refractive diagnostics which produces greater precision in refractive error. Iris data stored in conjunction with refractive diagnostic analysis provides a safety mechanism for subsequent treatment.
DESCRIPTION OF DRAWING(S) - The figure shows a block diagram illustrating acquisition of iris data in conjunction with refractive characteristic data.

Abstract (Basic): WO 200108547 A2

NOVELTY - An illumination system (20) projects excitation light energy (18) from a light energy source (16) into the corneal tissue (4) of an eye (2). The eye absorbs the excitation light energy, and produces and emits a fluorescent light energy (14). A detector (26) measures the intensity of the fluorescent light energy. A computer (30) determines the tissue surface shape based on the detector result.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

(a) a tissue surface region laser sculpting method;
(b) a tissue surface topography measuring system;
(c) a corneal tissue exposed surface topography measuring system;
(d) an exposed tissue surface laser sculpting system;
(e) a laser sculpting system for an ablated region on an exposed stromal tissue surface;
(f) a tissue hydration measuring system;
(g) a system used in an eye corneal tissue resculpting apparatus;
(h) a tissue hydration measuring method;
(i) a compensation method for use in resculpting an eye corneal tissue;
(j) and an eye corneal tissue sculpting method to attain a desired change in an eye optical property.

USE - For measuring surface shape or topography of e.g. eye corneal tissue, during reshaping of eye corneal tissue by eye surgical procedure e.g. **photo refractive** keratectomy PRK, photo therapeutic keratectomy PTK, laser-assisted in situ keratomileusis LASIK.

ADVANTAGE - Facilitates control of tissue reshaping process, since process relies on tissue surface shape **measurement** . Facilitates correction of **eye** refractive vision errors e.g. near or far sightedness, astigmatism. Attains intended eye corneal tissue shape. Eye hydration can be also measured, to ensure correct laser energy pattern applied to eye during actual eye hydration. Ensures effective laser sculpting of eye. Allows use of e.g. visible, ultraviolet or infrared lasers, deuterium lamps, arc lamps, as excitation light energy.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram of a surface topography system.

Eye (2)

Abstract (Basic): US 6089715 A
NOVELTY - The screening system and method uses a digital camera (10) having a lens (14) mounted flash (12), and a suitably programmed processor (18) for locating the eye of the patient (16) in the digital image, modeling structures in the eye, analyzing the digitized eyes in the individual for eye disease, and providing a recommendation for treatment.
USE - The invention can be used to provide information about an individuals eyes, and any possible diseases within the eyes. The processor can also possibly give a recommended course of action or treatment.
ADVANTAGE - This invention can spot possible problems within adults and children's eyes early and therefore reduce the risk of long term amblyopia.
DESCRIPTION OF DRAWING(S) - The drawing shows a block diagram showing the physical components of the eye imaging apparatus.

Abstract (Basic): WO 9918868 A

NOVELTY - The method involves directing a light beam at a region of an eye including portions of a sclera and an iris. A reflected light from the region of the **eye** is received for **measuring** an intensity of the reflected light to determine a relative position of the eye. DETAILED DESCRIPTION - An optical system (20) projects light onto a limbus (10) to track eye movement. The optical system (20) includes a light source (22) that directs a single or several light rays (24) through an optical train (26) onto the limbus (10) of the eye (2). The optical train (26) includes a scanning device (28) that scans the light rays (24) around a trajectory (29) that coincides with the limbus (10)..An INDEPENDENT CLAIM is included for:an optical system for tracking movement of eye of a patient

USE - The invention may be used for tracking the position of the eye during surgical procedures, such as **photo - refractive** keratectomy (PRK) photo-therapeutic keratectomy (PTK) laser in situ keratomileusis (LASIK) or the like.

ADVANTAGE - The present invention is capable of modifying spatial and temporal distribution of laser beam and accurately tracking eye movements in real time so that these movements can be compensated for during, for example, a laser ablation procedure. DESCRIPTION OF DRAWING(S) - The drawing is a block diagram of basic components of an optical system for performing a method of laser ablation according to the present invention. (10) limbus; (20) optical system; (22) light source; (24) light rays; (26) optical train.

Abstract (Basic): WO 9528989 A

The laser delivery and tracking mechanism includes a laser (500) which generates light (502) along a path at an energy level for treating a surface. An optical translator (520) shifts the path onto a resulting beam path. An optical angle adjuster (310,316,320,326) changes the angle of the resulting beam path relative to the original path such that the laser light is incident on the surface to be treated.

A motion sensor (100) transmits light energy (101-T) to the surface and receives reflected light energy (101-R) from the surface via the optical angle adjuster. The light energy travels on a parallel path to the shifted beam through the optical angle adjuster. The motion sensor detects movement of the surface relative to the original path and generates error control signals indicating the movement. The optical adjuster responds to the error control signals to change the angle of the resulting beam path.

USE/ADVANTAGE - Eroding moving surface e.g eye's corneal tissue in e.g **photo - refractive** keratectomy. **Eye** movement is **measured** quantitatively and used to automatically redirect both laser delivery and eye tracking parts of system independent of laser positioning mechanism. System operates without interfering with particular treatment laser or surgeon performing procedure.

Abstract (Basic): US 5249003 A

The ocular refractivity measuring apparatus includes a light receiving optical system, an illuminating optical system, an imaging device and a calculator. The light receiving optical system includes a light dividing member and an obturating plate. The obturating plate has a linear edge so as to obturate part of an opening of the light receiving optical system. The light dividing member is closer to a fundus of an **eye** to be **measured** in an optical path than the obturating plate. The illuminating optical system has a light source for projecting light in a direction perpendicular to the linear edge of the obturating plate, to the light dividing member so as to illuminate the fundus of the eye via the light dividing member.

The imaging device is provided on a light receiving surface of the light receiving optical system at a position substantially conjugate with a pupil of the eye for detecting the amount of light in two regions of the pupil of the eye separated in a direction perpendicular to the linear edge of the obturating plate. The calculator calculates the refractivity of the eye in accordance with the ratio of the amount of light in the two regions of the pupil of the eye separated in a direction perpendicular to the linear edge detected by the imaging device and in accordance with the distance between the two regions.

USE/ADVANTAGE - Can calculate the astigmatic angle, the degree of astigmatism, and the degree of spherical ametropia of an **eye** to be **measured** even if it has oblique astigmatism.

Abstract (Basic): US 6655605 N

The method and apparatus is for detecting human eye defects. The invention operates by recording on colour film the eye reflex which occurs when eyes are exposed to a flash of light. The photographs are compared with predetermined standards, to detect eye defects. The base structure of the ocular screening system (10) is a folding interconnect structure (12), comprising hinged sections (14,16,18).

Attached to one end of the structure is a head positioning station (24) which comprises vertical support (26), a head positioning bracket (28) having one end attached to the top of support, and two head positioning lamps (33) to verify precise head positioning. At the opposite end of the interconnect structure is a camera station (34) with camera (38), electronic flash unit (44) and blinking fixation lamp (46), for photographing the **eyes** of persons being **evaluated** .

USE - Partic. for detection of refractive error.

Priority Applications (No Type Date): US 73358246 A 19730507

Abstract (Basic): US 3879113 A

The eye testing apparatus has the light source as the tip of a fibre optic probe, and the restroreflected light is captured by a camera lens surrounding the probe. The **eye** defects are **quantified** by cylindrical sector lenses arranged pie-slice fashion around the probe, each of which forms the arm of a star pattern on the film which is a measure of the amount and kind of refractive error. The apparatus

is extended by the use of fixed reflectors on eyeglass frames so tha phoria may be measured from pupil spacing and position relative to the fixed images of the reflectors. The methods take advantage of inherent chromatic abberation of the eye.

ABSTRACT
PURPOSE: To improve the operation performance of a device using the **photorefraction** method by calculating the refraction force of an inspected eye by using the outputs of a pupil projection factor-detecting means in a focusing light-receiving optical system and an image pick-up element installed on the light receiving surface of the optical system.

CONSTITUTION: A half mirror 4, light shielding plate 5, lends 6, image pick-up element 7 which is conjugate with a pupil Ep with respect to the lens 6, and a video camera 14 are installed in this order in the optical path leading from the eye-ground Er of an inspected eye. Through the lens 6, light is focused in the direction of arrow by a driving part 15, and the position information is inputted into a calculator 20, and the pupil projection factor is detected. Into the calculator 20, the output of the video camera 14 is inputted, besides the position information of the lends 6, and the light quantity ratio or contrast in two regions of the pupil is calculated, and the refraction force of the inspected eye is calculated on the basis of the light quantity ratio or contrast. Accordingly, in the refraction force measurement using the **photorefraction** method, the operation distance between the inspected eye and the device body can be set arbitrarily, and adjustment has only to be made of the focus optical system in this state, and the operation performance can be improved drastically.

JOURNAL: Section: C, Section No. 892, Vol. 15, No. 484, Pg. 77, December 09, 1991 (19911209)

ABSTRACT

PURPOSE: To execute the **eye** refracting power **measurement** with high accuracy by a **photorefraction** method by calculating the examined eye refracting power, based on a light quantity ratio detected by an image pickup element in two areas of an examined eye pupil separated by a prescribed distance in the direction intersecting with a linear edge of a light shielding plate.

CONSTITUTION: In a light receiving optical system, a light splitting member 4, and light shielding plates 5, 3 having a linear edge 50 so as to obstruct a part of an opening of the optical system are provided in order in an optical path from an eyeground Er of an eye E to be examined. Also, in an irradiating optical system, a light source part 1 is provided in the direction intersecting with the edge 50 and the eyeground Er of the eye to be examined is irradiated through the light splitting member 4. Moreover, an image pickup element 7 is provided on the light receiving surface of the above-mentioned light receiving optical system being in a roughly conjugate position to the pupil Ep of the eye. In such a state, in a computing element 20, the examined eye refracting power is calculated, based on a light quantity ratio or contrast detected by the image pickup element 7 in two areas of the pupil Ep of the eye separated by a prescribed distance in the direction intersecting with the linear edge 50. Thus, the **eye** refracting power **measurement** can be executed with high accuracy with a **photorefraction** method.

JOURNAL: Section: C, Section No. 811, Vol. 15, No. 92, Pg. 125, March 06, 1991 (19910306)

ABSTRACT

PURPOSE: To make a measurement with high accuracy possible by judging strength of a reflecting light in a pupil based on a shade pattern of a

pupil image and an iris image and **measuring** an **eye** refractive value.

CONSTITUTION: When an examined eye E is normal, all the light bundles from a pupil Ep are received on a lens and reach a recording medium 3 and the whole area in a pupil image P surrounded by an Aris image I on the recording medium 3 becomes bright. When the examined eye F is iongsightedness, a reflected light bundle from an eyeground Er disperses when it passes through the pupil and as only a light bundle from the central part of the pupil Ep reaches the lens 2, only the central part of the pupil image P on the recording medium 3 becomes bright. When the examined eye E is shortsightedness, as the reflected light bundle from the eyeground Er is condensed before a half mirror 1 after it passes through the pupil Ep and reaches the lens 2, only upper part of the pupil image P on the recording image 3 becomes bright. As described above, as a shade pattern of the pupil image P in the iris image 1 on the recording medium 3 becomes different depending on the refractive value of the pupil Ep of the examined **eye** E, **measurement** of **eye** refractive value can be done based on this shade pattern by using a pattern detecting device and an arithmetic device.

Abstract (Basic): WO 200027273 A1

NOVELTY - Eye-safe light beams are directed onto the eye such that area of incidence is substantially larger then the pupil. The image of light beam reflected is analyzed by extracting light beam components that produce bright eye reflection in received image. The position of **eye** is **determined** by further analyzing the image on the basis of identification.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for eye tracker.

USE - For ophthalmic laser surgery for refractive correction in eye such as **photorefractive** keratectomy, laser in-situ keratomileusis and for gaze analysis application for ablating minute portions of cornea tissue.

ADVANTAGE - Facilitates tracking of eye movement in real time so that laser source is controlled to compensate for eye movement.

DESCRIPTION OF DRAWING(S) - The figure illustrates relevant components of ophthalmic surgery apparatus.

English Abstract
Methods and apparatus for improving vision incorporate the effects of biodynamical and biomechanical (biological) responses of the eye. The eye produces a biological response to trauma, such as a LASIK keratectomy or other necessary traumatic procedure in preparation for refractive surgery. By observing the biological response, a prospective treatment to correct higher order aberrations is adjusted to compensate for the biological effects. An improved photorefractive surgery system incorporates one or more suitable diagnostic devices that provide biological response information in such a manner that the patient need not change position from that assumed for the surgical procedure.

English Abstract
Ocular refraction is determined from wavefront aberration data, and an optimum customized correction is designed. The eye's wave aberration is measured (202) by using a detector such as a Shack-Hartmann detector (714). From the aberration, an image metric is calculated (214), and the second-order aberrations which optimize that metric are determined (218). From that optimization, the refractive correction (220) required for the eye is determined. The image metric is one of several metrics indicating the quality of the image on the retinal plane or a proxy for such a metric. The required refractive correction (220) can be used to form a lens or to control eye surgery. If it is possible to detect more aberrations than can be corrected, those aberrations are corrected which most affect vision, or for which the eye's error tolerance is lowest.

English Abstract
A system and method are provided in which an iris or eye image is taken during a refractive diagnostic analysis. The image is employed for aligning data from the analysis with data from other refractive analysis instruments, as well as aligning a refractive surgical tool, such as a laser, with the eye for treatment. Further, the stored iris image is compared with the patient's iris before treatment, verifying that the correct eye is to be treated with a developed treatment pattern. A variety of refractive instruments can be used, such as corneal topography systems and wavefront aberration systems.

English Abstract
A system and method for locating and modeling eyes in imagery for automated **photorefractive** screening. The invention includes a system and method for locating a patient's (16) eyes in a digital image that includes each eye as illuminated by a near-axis flash (12), including automatically finding light reflexes in the digital images as indicative of the location of each eye. Automatically finding light reflexes includes analyzing such light reflexes to determine possible pupil and sclera borders. The invention further includes automatically fitting a corresponding model to such possible pupil and sclera borders, analyzing the model of each **eye** to **determine** possible abnormalities in each eye; and outputting a possible diagnosis for each eye based on such analyzing. Other aspects of the invention include measuring retinal reflexes and corneal reflexes from the indicated eye models as an indicator of anomalies in the patient's (16) eyes, and generating a digital image of each of a patient's (16) eyes with a camera having a flash (12) positioned near to a center line of a lens of the camera (10) so as to generate images with bright, sharp light reflexes.

Detailed Description
AUTOMATED PHOTOREFRACTIVE SCREENING
TECHNICAL FIELD
This invention relates to instruments for **measuring** characteristics of **eyes** , and more particularly to a system and method for locating and modeling eyes in imagery for automated **photorefractive** screening, and for enabling determination of the presence of anomalies in the patient's visual...the face of an and a suitably programmed processor, such as a general purpose digital **computer** , for locating an **eye** of the individual in the digital image, modeling structures in the eye, analyzing the digitized...

English Abstract
The invention is a corneal topographer (240) based on cornea-scope holography with partially coherent illumination. Corneal topographic measurements can be accomplished at a processing rate higher than the standard video rate of 30 Hz. The corneo-scope measurements can be used in an optic electronic servo (220) to control photo-refractive keratectomy system (200) in real time for an improved accuracy in laser ablation of a corneal surface of the eye (230).

Claim

... is system, and said topographer, said controller controlling said topographer to achieve a corneal topographic **measurement** of said target **eye** at a processing rate higher than said pulse repetition rate.

I 10. A system as...

...wherein said ablating laser beam is controlled by said controller based on said corneal topographic **measurement** of said target **eye** .

11 A system as in claim 10, wherein said control of said ablating laser beam...

Bad Data

English Abstract
An apparatus and method for measuring refractive characteristics of human eyes with an objective refraction measuring device for measuring refraction in at least one eye, the objective refraction measuring system (10) having a proximal end and a distal end, the objective refraction measuring system suitable for looking in the proximal end and seeing out the distal end; an open field visual target (50). A viewing lane (20) is provided between the eye (42) and (44) the open field visual target (50), the viewing lane has sufficient length to allow for focusing the eye at infinity and for natural accommodation at true distance targets, such near distances such as reading distances. The objective refraction measuring device can be positioned in the viewing lane to measure the eye while the eye is focused on the open field visual target. In one embodiment the objective refraction measuring device may measure refraction characteristics of an eye continuously, substantially continuously or incrementally during dynamic accommodation or changes of the lighting conditions while providing true distance visual targets with the open field of view through the apparatus. In another embodiment the device objectively measures refraction characteristics of both eyes working together when viewing the open field visual target.

Title: Multimeridian photorefraction: a technique for the detection of visual defects in infants and preverbal children
Author(s): Cole, T.D.
Journal: Johns Hopkins APL Technical Digest vol.12, no.2 p.166-75
Publication Date: April-June 1991 Country of Publication: USA
CODEN: JHADDQ ISSN: 0270-5214
Abstract: The Applied Physics Laboratory and the Department of Ophthalmology at the Johns Hopkins Medical Institutions have collaborated in a two year effort to identify and develop techniques based on photorefraction for the visual screening of young children. This article briefly discusses visual screening concerns and photorefractive theory and techniques. Difficulties associated with the **measurement** of **visual** defects using conventional **photorefractors** are identified, and the Laboratory's efforts to design two photorefractors intended to overcome the limitations of previous instruments are described along with the operating principles of the two prototypes. An introduction to laser retinoscopy is also presented. Research on a more comprehensive device-a multimeridian laser retinoscope-is under way. (20 Refs)

ABSTRACT: Background: In contrast to incisional keratotomy, corneas that have undergone photorefractive keratectomy may be difficult to detect by inspection with slitlamp biomicroscopy alone. Eye bank corneas that have undergone high myopic refractive surgical correction could potentially result in substantial postoperative hyperopic correction if used as donor tissue for corneal transplantation. Surface irregularities or displacement of the treated optical zone within the graft in relation to the entrance pupil of the recipient could result in significant induced astigmatism and distortion. This study examines computerized videokeratographic screening of eye bank globes as a strategy for detecting myopic photorefractive keratectomy. Methods: Preoperative and postoperative corneal topographic maps of freshly enucleated human and rabbit eyes that have undergone myopic photorefractive keratectomy with an excimer laser were placed in a globe-fixating device and analyzed using a vertically oriented videokeratoscope. The same system was applied in an actual eye bank setting, and potentially transplantable globes from donors without a history of corneal surgery were analyzed. Results: Computerized videokeratography using a vertically mounted system

reliably detected photorefractive keratectomy in 12 of 12 human eye bank corneas treated by excimer photorefractive keratectomy in a range between -1.5 to -6.0 diopters. This method also detected similar changes on lased rabbit corneas enucleated 6 weeks after excimer surgery. Data processed with the tangential mode yielded a "bull's-eye" topography pattern reflecting central corneal flattening that was more sensitive in detecting myopic corrections than the conventional axial formula-based color maps. False-positive results were not detected in 96 cadaver globes sequentially screened in the eye bank. Conclusions: Computerized videokeratogaphy represents a feasible method to screen donor globes for myopic photorefractive keratectomy as shown by the in vitro and rabbit models. However, only whole globes and not corneoscleral sections are amenable to processing with this technique. Tangential maps provided greater sensitivity in detecting low myopic corrections than the axial formula-based color maps.

Purpose: The purpose of this study was to compare with computer simulations the duration, smoothness and accuracy of scanning photo-refractive keratectomy with spot diameters ranging from 0.2 to 1 mm. Methods: We calculated the number of pulses per diopter of flattening for spot sizes varying from 0.2 to 1 mm. We also computed the corneal shape after the correction of 4 diopters of myopia and 4 diopters of astigmatism with a 6 mm ablation zone and a spot size of 0.4 mm with 600 mJ/cm SUP 2 peak radiant exposure and 0.8 mm with 300 mJ/cm SUP 2 peak radiant exposure. The accuracy and smoothness of the ablations were compared. Results: The repetition rate required to produce corrections of myopia with a 6 mm ablation zone in a duration of 5s per diopter is on the order of 1 kHz for spot sizes smaller than 0.5 mm, and of 100 Hz for spot sizes larger than 0.5 mm. The accuracy and smoothness after the correction of myopia and astigmatism with small and large spot sizes were not significantly different. Conclusions: This study seems to indicate that there is no theoretical advantage for using either smaller spots with higher radiant exposures or larger spots with lower radiant exposures. However, at fixed radiant exposure, treatments with smaller spots require a larger duration of surgery but provide a better accuracy for the correction of astigmatism.

One-way image transmission through a thick dynamic distorter without a reference beam
ZHANG Jiasen; WANG Huitian; YOSHIKADO Shin; ARUGA Tadashi
Journal: Applied physics letters, 1998-02-09, 72 (6) 630-632
ISSN: 0003-6951 CODEN: APPLAB Availability: INIST-10020
We demonstrated a method to perform one-way image transmission through a dynamic distorter without a reference beam. In this method, a photorefractive four-wave mixing configuration was used to pick up the reconstructed image from the image-bearing signal beam, which acted as an erase beam. The fluctuation period of the dynamic distorter must be much shorter than the response time of the nonlinear material. Reconstructed images with high-fidelity have been obtained. Because use of a reference beam is unnecessary this method is simpler and more effective. (c) 1998 American Institute of Physics.

The constant progress in photorefractive surgery requires measurement devices with which the topography of the cornea can be measured with a high precision and bigger reproducibility than the currently used devices offer. The special two-path moire deflectometer is constructed for in vivo measurements. To overcome the problem associated with rapid eye movements, the special unit for measurement of the distance between the eye and the experimental setup, is designed. The achievable resolution of the proposed topographer is in the range of about 3 microns within a lateral measurement range of about 5 mm in diameter. The corresponding precision of the spherical equivalent dioptric number is thus better than 0.015D.

Acute overlapping of successive laser pulses onto the cornea during photorefractive keratectomy (PRK) is important to avoid refractive distortions. Most excimer laser systems performing corneal ablation lack control of the patient's eye movements and they cannot track the target corneal zone. We developed an eye-tracker based on television monitoring of the pupil and on automatic electro-mechanical deflection of the laser turning mirror, and we applied it to the ExciMed UV200 ArF work station (Summit Technology, Inc., Waltham, Mass.). Basic components are a black and white CCD camera and two fast stepping motors. The circuitry for target discrimination and tracking, and the optical imaging system are designed specifically. The tracker assembly does not interfere with the laser beam path nor with the operator's observation. Tracking of the pupil has been successfully achieved on different color irides, with an accuracy better than 0.1 mm in a 6 x 6 mm2 tracking field. Response time is less than 100 ms. Recordings of eye movements during PRK are presented. Tracking ablations have been performed on moving test eye-balls with plastic corneas. The proposed automatic system appears to be a reliable and effective method for the compensation of patient eye movements appears to be a reliable and effective method during PRK procedures.

Calculated impact of higher-order monochromatic aberrations on retinal image quality in a population of human eyes .
Guirao Antonio; Porter Jason; Williams David R; **Cox Ian G**
Journal of the Optical Society of America. A, Optics, image science, and vision (United States) Mar 2002, 19 (3) p620-8, ISSN 1084-7529
Journal Code: 9800943
Contract/Grant No.: EY01319; EY; NEI; EY04367; EY; NEI
Republished from J Opt Soc Am A Opt Image Sci Vis. 2002 Jan;19(1) 1-9; Republished from PMID 11778709
We calculated the impact of higher-order aberrations on retinal image quality and the magnitude of the **visual** benefit expected from their correction in a large population of human **eyes** . Wave aberrations for both **eyes** of 109 normal subjects and 4 keratoconic patients were measured for 3-, 4-, and 5.7-mm pupils with a Shack-Hartmann sensor. Retinal image quality was estimated by means of the modulation transfer function (MTF) in white light. The **visual** benefit was calculated as the ratio of the MTF when the monochromatic higher-order aberrations are corrected to the MTF corresponding to the best correction of defocus and astigmatism. On average, the impact of the higher-order aberrations for a 5.7-mm pupil in normal **eyes** is similar to an equivalent defocus of approximately 0.3 D. The average **visual** benefit for normal **eyes** at 16 c/deg is approximately 2.5 for a 5.7-mm pupil and is negligible for small pupils (1.25 for a 3-mm pupil). The benefit varies greatly among **eyes** , with some normal **eyes** showing almost no benefit and others a benefit higher than 4 at 16 c/deg across a 5.7-mm pupil. The benefit for keratoconic **eyes** is much larger. The benefit at 16 c/deg is 12 and 3 for 5.7- and 3-mm pupils, respectively, averaged across four keratoconics. These theoretical benefits could be realized in normal viewing conditions but only under specific conditions.

Contract/Grant No.: EY01319; EY; NEI; EY04367; EY; NEI
The use of a correcting element to compensate for higher-order aberrations in an optical system often requires accurate alignment of the correcting element. This is not always possible, as in the case of a contact lens on the **eye** . We propose a method consisting of partial correction of every aberration term to minimize the average variance of the residual wave-front aberration produced by Gaussian decentrations (translations and rotations). Analytical expressions to estimate the fraction of every aberration term that should be corrected for a given amount of decentration are derived. To demonstrate the application of this method, three examples are used to compare performance with total and with

partial correction. The partial correction is more robust and always yields some benefit regardless of the amount of decentration.

Monochromatic aberrations of the human eye **in a large population.**
Porter J; Guirao A; **Cox I G** ; Williams D R
Journal of the Optical Society of America. A, Optics, image science, and vision (United States) Aug 2001, 18 (8) p1793-803, ISSN 1084-7529 Journal Code: 9800943
Contract/Grant No.: EY01319; EY; NEI; EY07125; EY; NEI
From both a fundamental and a clinical point of view, it is necessary to know the distribution of the **eye** 's aberrations in the normal population and to be able to describe them as efficiently as possible. We used a modified Hartmann-Shack wave-front sensor to measure the monochromatic wave aberration of both **eyes** for 109 normal human subjects across a 5.7-mm pupil. We analyzed the distribution of the **eye** 's aberrations in the population and found that most Zernike modes are relatively uncorrelated with each other across the population. A principal components analysis was applied to our wave-aberration measurements with the resulting principal components providing only a slightly more compact description of the population data than Zernike modes. This indicates that Zernike modes are efficient basis functions for describing the **eye** 's wave aberration. Even though there appears to be a random variation in the **eye** 's aberrations from subject to subject, many aberrations in the left **eye** were found to be significantly correlated with their counterparts in the right **eye** .

Effect of rotation and translation on the expected benefit of an ideal method to correct the eye **'s higher-order aberrations.**
Guirao A; Williams D R; **Cox I G**
Journal of the Optical Society of America. A, Optics, image science, and vision (United States) May 2001, 18 (5) p1003-15, ISSN 1084-7529 Journal Code: 9800943
Contract/Grant No.: EY01319; EY; NEI; EY04367; EY; NEI
Document type: Journal Article
An ideal correcting method, such as a customized contact lens, laser refractive surgery, or adaptive optics, that corrects higher-order aberrations as well as defocus and astigmatism could improve **vision** . The benefit achieved with this ideal method will be limited by decentration. To estimate the significance of this potential limitation we studied the effect on image quality expected when an ideal correcting method translates or rotates with respect to the **eye** 's pupil. Actual wave aberrations were obtained from ten human **eyes** for a 7.3-mm pupil with a Shack-Hartmann sensor. We computed the residual aberrations that appear as a result of translation or rotation of an otherwise ideal correction. The model is valid for adaptive optics, contact lenses, and phase plates, but it constitutes only a first approximation to the laser refractive surgery case

where tissue removal occurs. Calculations suggest that the typical decentrations will reduce only slightly the optical benefits expected from an ideal correcting method. For typical decentrations the ideal correcting method offers a benefit in modulation 2-4 times higher (1.5-2 times in white light) than with a standard correction of defocus and astigmatism. We obtained analytical expressions that show the impact of translation and rotation on individual Zernike terms. These calculations also reveal which aberrations are most beneficial to correct. We provided practical rules to implement a selective correction depending on the amount of decentration. An experimental study was performed with an aberrated artificial **eye** corrected with an adaptive optics system, validating the theoretical predictions. The results in a keratoconic subject, also corrected with adaptive optics, showed that important benefits are obtained despite decentrations in highly aberrated **eyes** .

Visual **benefit of correcting higher order aberrations of the** eye .

Williams D; Yoon G Y; Porter J; Guirao A; Hofer H; **Cox I**

Journal of refractive surgery (Thorofare, N.J. : 1995) (UNITED STATES) Sep-Oct 2000, 16 (5) pS554-9, ISSN 1081-597X Journal Code: 9505927

Contract/Grant No.: EY01319; EY; NEI; EY04367; EY; NEI

There is currently considerable debate concerning the **visual** impact of correcting the higher order aberrations of the **eye** . We describe new measurements of a large population of human **eyes** and compute the **visual** benefit of correcting higher order aberrations. We also describe the increase in contrast sensitivity when higher order aberrations are corrected with an adaptive optics system. All these results suggest that many, though not all, observers with normal **vision** would receive worthwhile improvements in spatial **vision** from customized **vision** correction, at least over a range of viewing distances and particularly when the pupils are large. Keratoconic patients or patients suffering from spherical aberration as a result of laser refractive surgery as it is presently performed would especially benefit. These results encourage the development of methods to correct higher order aberrations. (14 Refs.)

Histopathology of childhood pneumonia in developing countries.

Anderson V M; **Turner T**

Reviews of infectious diseases (UNITED STATES) May-Jun 1991, 13 Suppl 6 pS470-6, ISSN 0162-0886 Journal Code: 7905878

Acute lower respiratory infection in children is a major cause of morbidity and mortality in developing countries. Viral and bacterial agents incite characteristic host responses at the level of the bronchi, bronchioles, alveolar walls, and air spaces that correlate with the clinical course. A systematic review of histopathologic features will enhance the understanding of the pathogenetic mechanisms and cofactors that influence the disease process, particularly how tissue injury may be

influenced by nutritional status and access to antibiotics. Research priorities include immunologic assessment, micronutrient assays, and standardized autopsies in developing countries. DNA probes for organisms and immunocytochemical identification of cell markers in tissue promise a new era in microscopic **visualization** of pathogen-host interactions. International collaborative research between ministries of public health and medical universities must be encouraged as a means of providing technical assistance and of advancing new knowledge. Systematic standardized autopsy studies from multiple geographic areas may help define pathologic mechanisms, monitor the natural history of disease, and evaluate interventions in diverse populations. Effects of sighting and sensory dominance on monovision high and low contrast visual **acuity.**

Robboy M W; **Cox I G** ; Erickson P

CLAO journal : official publication of the Contact Lens Association of Ophthalmologists, Inc (UNITED STATES) Oct-Dec 1990, 16 (4) p299-301, ISSN 0733-8902 Journal Code: 8302065

We investigated the relationship between ocular dominance and monovision **visual** performance in 15 presbyopic subjects. Ocular dominance was determined using sighting (hole-in-the-card and mirror tests) and sensory (anisometropic blur suppression test) methods. Correcting the dominant sighting **eye** for a given viewing distance was found to be an unreliable method of optimizing blur suppression or binocular high/low contrast **visual** acuity at that distance. If there is any advantage to a particular strategy for selecting the distance monovision **eye** , it must be realized in **vision** performance areas other than **visual** acuity.

Soft contact lens-induced longitudinal spherical aberration and its effect on contrast sensitivity.

Cox I ; Holden B A

Optometry and vision science : official publication of the American Academy of Optometry (UNITED STATES) Sep 1990, 67 (9) p679-83, ISSN 1040-5488 Journal Code: 8904931

Some investigators have suggested that the poor quality of **vision** which some spherical, single **vision** , soft lens-wearing patients report may be a result of spherical aberration induced in the ocular system when a soft lens is placed on the **eye** . In this study, the longitudinal spherical aberration of spherical soft lenses, both on and off the **eye** , was calculated using an aspheric corneal model and two-dimensional ray tracing program. Specifically designed front-surface aspheric, soft lenses were produced which demonstrated levels of in-air power variation similar to that calculated for similar-parameter spherically surface lenses. The effect of these lenses on the **visual** performance of nine subjects was assessed by measuring changes in contrast sensitivity and high contrast

visual acuity through 3- and 6-mm artificial pupils. Significant losses of contrast sensitivity were recorded for the spherically aberrated lenses with the 6-mm pupil but not with the 3-mm pupil. High contrast acuity was not affected by any of the aberrated lenses with either the 3- or 6-mm pupils. Theoretical calculations and the contrast sensitivity results indicate that negatively powered lenses produce significantly less spherical aberration in situ than positively powered lenses. Because the majority of the prepresbyopic soft lens-wearing population have low to moderate amounts of myopia, it would appear that soft lens-induced spherical aberration is unlikely to be responsible for the reduction in **visual** performance which some patients report when corrected with single **vision** soft lenses.

DIALOG(R)File 155:MEDLINE(R)

06559709 90259524 PMID: 2342790

Theoretical calculation of the longitudinal spherical aberration of rigid and soft contact lenses.

Cox I

Optometry and vision science : official publication of the American Academy of Optometry (UNITED STATES) Apr 1990, 67 (4) p277-82, ISSN 1040-5488 Journal Code: 8904931

Although previous investigators have attempted to calculate the longitudinal spherical aberration inherent in soft and rigid contact lenses both on and off the **eye** , the use of inappropriate assumptions on which to base their calculations has left the problem unresolved. In this study, the longitudinal spherical aberration of both soft and rigid contact lenses was calculated surface by surface both in air and on the **eye** using a two-dimensional, exact ray tracing program. The erroneous assumptions made by previous investigators were avoided by using an elliptical model for the anterior corneal surface and assuming that the posterior surfaces of soft lenses aligned exactly with the anterior corneal surface after flexure onto the **eye** . The results demonstrated that, with a 6-mm pupil, contact lenses induce significant levels of spherical aberration in the ocular system for soft lenses of back vertex power greater than +3.00 D or -6.00 D and for rigid lenses of powers more positive than -3.00 D. It is suggested that **visual** disturbance due to induced spherical aberration has not been a major clinical problem in the past because these conditions fall outside those experienced by a large proportion of the contact lens-wearing public.

Effect of eye **patching on the overnight corneal swelling response with rigid contact lenses.**

Cox I ; Ames K

Optometry and vision science : official publication of the American Academy of Optometry (UNITED STATES) Apr 1989, 66 (4) p207-8, ISSN 1040-5488 Journal Code: 8904931

In this study, 23 subjects wore a rigid extended wear (EW) lens overnight with a light pressure patch covering the **eye** while 19 subjects wore the

same type of lens without patching. Corneal thickness measurements taken immediately upon awakening showed no significant difference in corneal swelling between the two groups. This result indicates that light pressure patching does not significantly affect the overnight corneal swelling found with rigid EW lenses, and it suggests that lagophthalmos during contact lens wear does not contribute significantly to the oxygen reaching the cornea during the closed- **eye** phase of overnight swelling studies.
